Solid silica precipitation, growth and deposition in depressurized supercritical steam

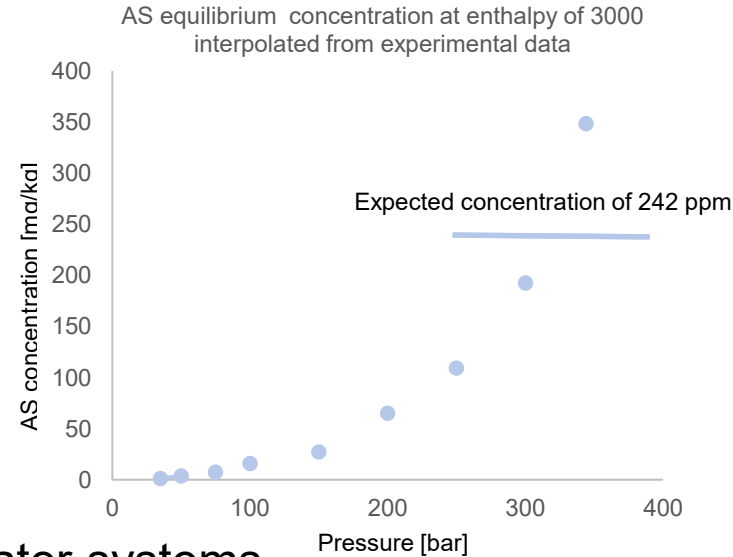

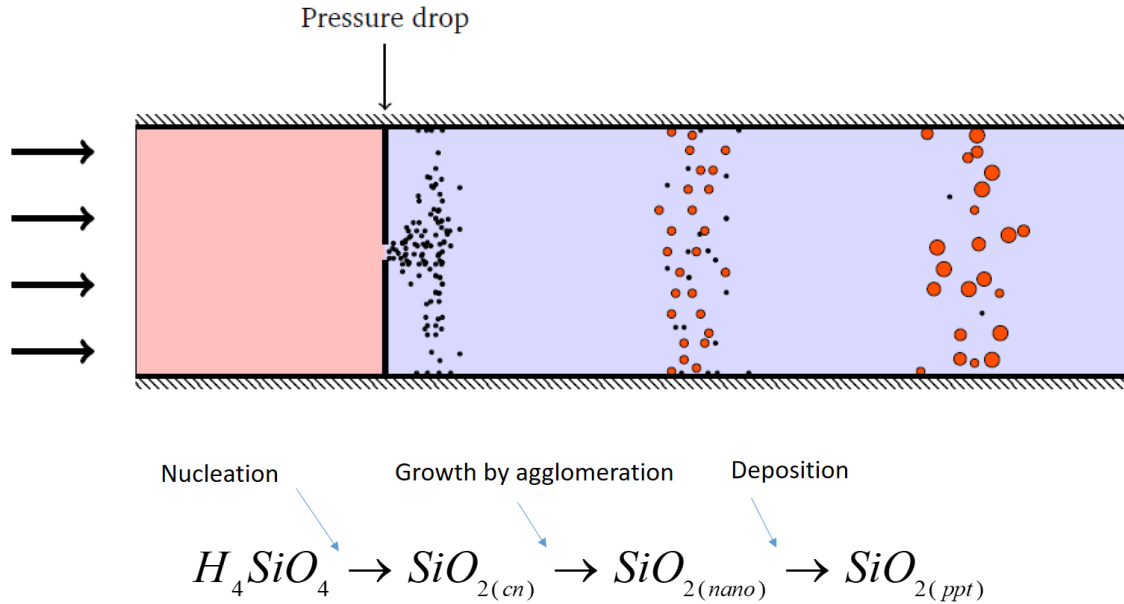

Silje Bordvik- CGER 16.02.2023

Project background

- Research project by NTNU in cooperation with IFE, Forskningsrådet, and Equinor through their investment in IDDP project and;
- Deep Geo
- Solubility

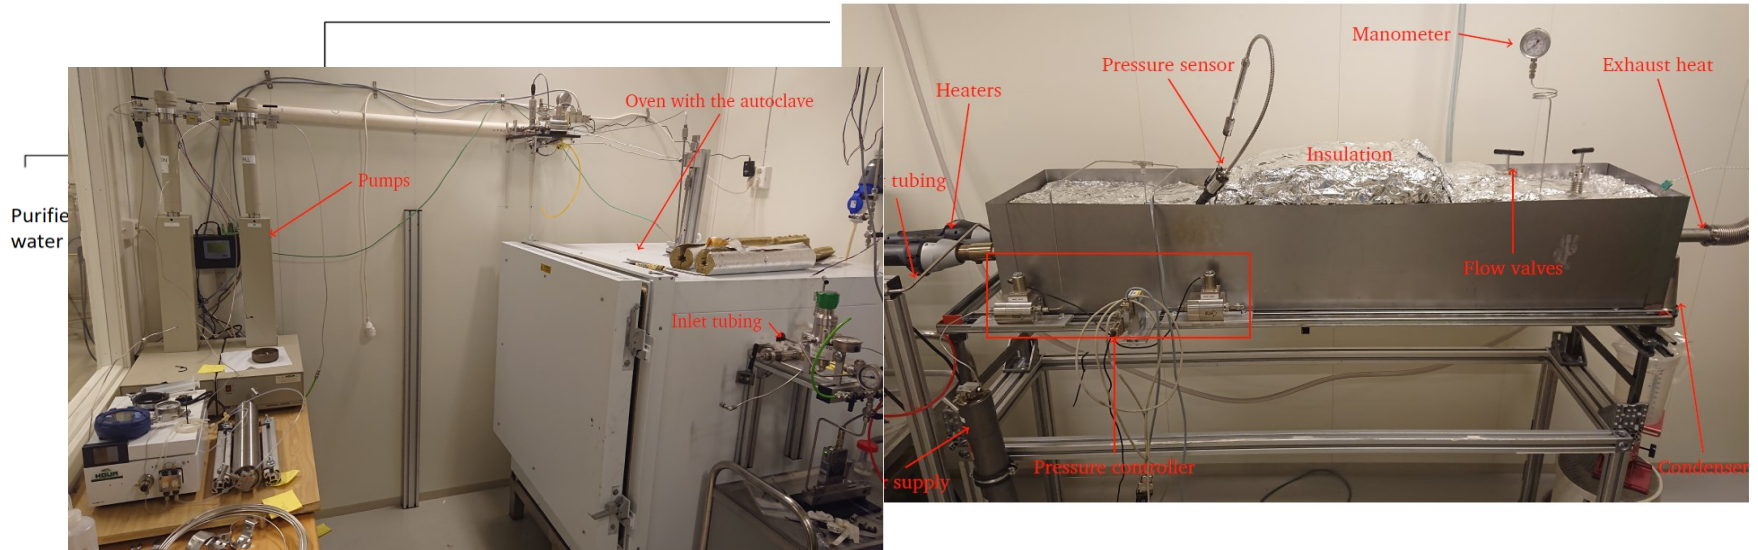

What happens upon depressurization?

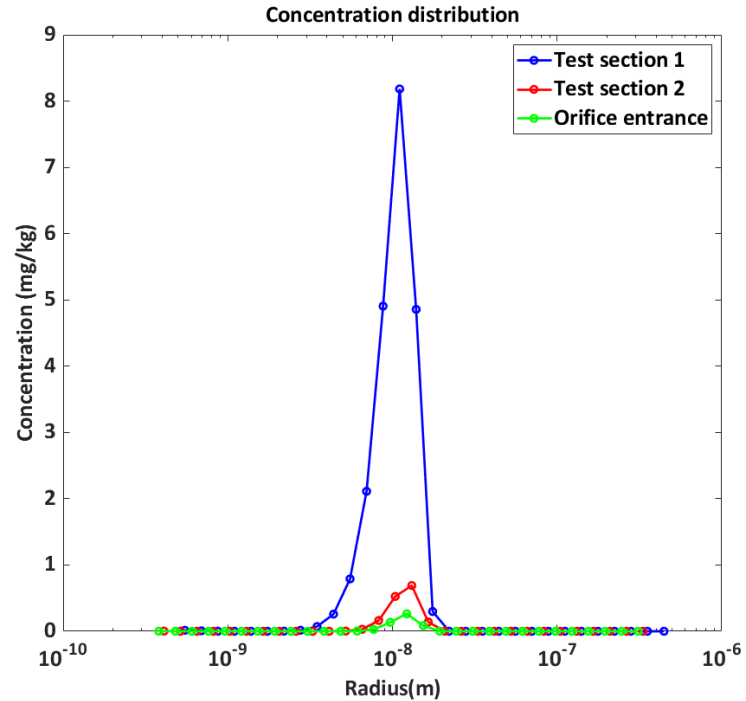

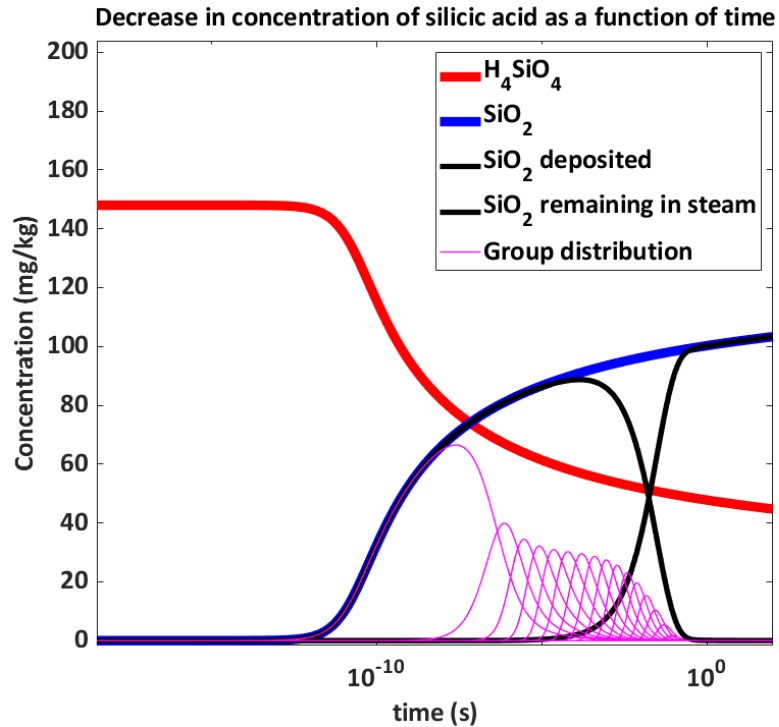

- How this case differ from silica precipitation in water systems

Experimental setup

- Test rig built at NTNU- connected to a autoclave inside a heater at IFE (Morten Tjelta)

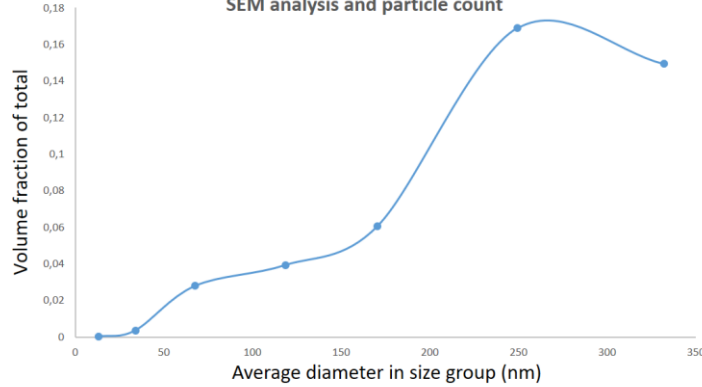

Modelled results

Photos of orifice

Volume fraction distribution into particle size groups based on SEM analysis and particle count

x50,000 5.0kV LED SEM 100nm WD 6.2mm

x50,000 5.0kV LED SEM 100nm IFE WD 5.5mm

Measurements

- Tests were done for test pressures ranging from 76 to 150 bar and Reynolds numbers ranging from 1000 to 10 000
- Deposited material- differential weight of each test section before and after experiment
 - High relative uncertainties for the short duration tests
- Deposition rate in mg SiO₂ per surface area per second

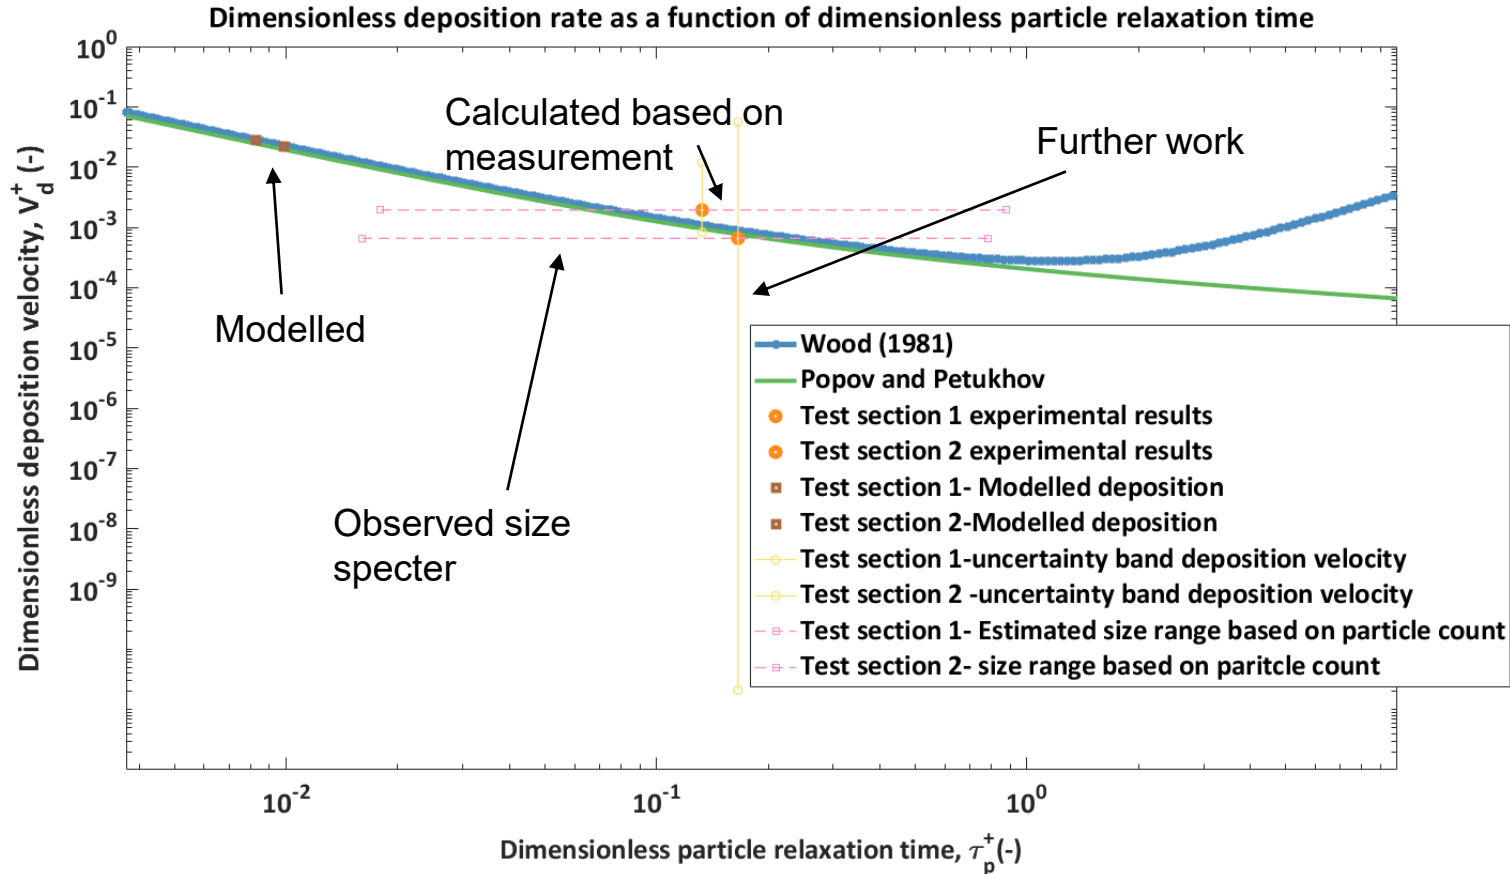

$$J = \frac{\Delta m}{A_{\text{surface}} \cdot \text{duration}} \left[\frac{\text{mg}}{\text{m}^2 \text{s}} \right]$$

$$V_d^+ = \frac{J}{c_{\text{SiO}_2} u_\tau} = \frac{\dot{m}}{c_{\text{SiO}_2} u_\tau A}$$

$$\tau^+ = \tau \frac{u_*^2}{\nu} = \frac{\rho_p d_p^2}{18 \rho_l \nu} \left(\frac{u_\tau}{\nu} \right)^2$$

Comparison of results

Test Pressure: 98 bar
Re:10 406

Preliminary Conclusions

- Most tests indicate a better fit with the observed average radius than the calculated radius
- Comparing the first and second test section, the relatively high measured deposition in test section two also indicate that the concentration will have had to be significant and therefore the previous deposition lower than expected
- No safe upper pressure for which silica will not precipitate above is indicated. Rather particle size and concentration is affected by the supersaturation
- The nature and predictability in modelling of the silica scaling process make controlled precipitation in the steam phase an interesting topic for further investigation in this HPHT case, as the energy gain can be significant compared to quenching in liquid to remove silica
